PROFILE

Software Engineer with experience building backend services, AI-enabled application workflows, and data-driven product features across web and cloud environments. I have worked on production-oriented APIs, document ingestion flows, recommendation logic, authentication systems, file handling pipelines, and analytics-related features that support real user workflows. My work has involved designing maintainable backend modules, integrating external AI and search services, improving reliability through validation and debugging, and collaborating with teams to turn product requirements into practical technical solutions. I am especially interested in building scalable software that combines backend engineering, intelligent systems, and structured data workflows to solve meaningful business problems.

SKILLS

Languages

Python • Java • JavaScript • TypeScript • SQL • PL/SQL • C++ • HTML • CSS

Backend & Application Development

Node.js • Express.js • FastAPI • Spring Boot • REST APIs • Authentication • JWT • Validation • Error handling • File processing • API integrations

AI & Data Workflows

LLM integrations • Prompt engineering • RAG • Embeddings • Vector search • Semantic retrieval • Structured outputs • Document ingestion • Recommendation workflows • Analytics features

Databases & Cloud

PostgreSQL • MySQL • MongoDB • Oracle • SQL Server • Firebase Realtime DB • Azure Blob Storage • Azure OpenAI • Azure AI Search • AWS • Docker

Tools & Engineering Practices

Git • GitHub • GitHub Actions • Jenkins • Linux • Postman • Jira • Debugging • Testing • Technical documentation • Agile development

PROFESSIONAL EXPERIENCE

HiEd Success

Software Engineer

May 2025 – Present

Atlanta, GA, USA

Tech Environment: Node.js, Express.js, MongoDB, Azure Blob Storage, REST APIs, JWT, AI and search integrations

- Contributed to the backend development of a career intelligence platform by building and maintaining APIs, business workflows, and service logic across multiple application areas including candidate onboarding, employer workflows, search, dashboard experiences, profile management, and recommendation-driven features. My work focused on making backend flows more reliable, maintainable, and aligned with product requirements that directly impacted end-user experience.
- Worked on resume parsing, job description parsing, and candidate-job matching workflows by integrating the platform with external AI and search services. Helped support the extraction of structured profile information, role relevance signals, and recommendation data that improved how users discovered jobs, how employers evaluated candidates, and how the platform surfaced stronger matching outcomes.
- Designed and enhanced protected REST endpoints for core application workflows including authentication, OTP verification, password reset, profile retrieval, saved jobs, application tracking, and notifications. Built these services with attention to request validation, middleware-based authorization, controller separation, and clear service behavior so that the backend remained easier to extend and support over time.
- Supported occupation and career analytics features by integrating recommendation inputs such as personality-based flows, salary trend lookups, occupation-oriented insights, and matching-related data. These features helped connect backend data processing with more meaningful dashboard outputs and user-facing suggestions, making the platform more useful as a decision-support tool rather than just a transactional application.
- Worked on file and document handling workflows for resumes, profile assets, and job-related uploads using multipart processing and Azure Blob Storage integrations. Helped improve parser-driven ingestion reliability and supported downstream workflows that depended on structured document processing, storage consistency, and cleaner backend handling of uploaded assets.
- Improved platform stability and maintainability by contributing to route-controller separation, request validation, error handling, API cleanup, and operational integrations such as transactional emails and supporting workflows. Regularly debugged production-facing issues, investigated failures across connected systems, and worked with teammates to deliver fixes that reduced friction during active release cycles.
- Collaborated in a fast-moving engineering environment where I had to understand business requirements quickly, work across unfamiliar modules, connect frontend and backend flows, and support iterative enhancements across analytics, search, parsing, matching, and user engagement experiences. This role strengthened my ability to work across systems, learn quickly, and deliver backend solutions that were both practical and product-oriented.

Tech Environment: JavaScript, full-stack application development, internal workflow systems

- Completed a 6-month internship in an aerospace-focused engineering organization where I contributed to the development of an internal pass distribution system used for registration, request processing, approval workflows, and status tracking. The work gave me experience operating in a structured environment where reliability, process alignment, and clarity of workflow behavior were important.
- Built and enhanced application modules across the frontend and backend to support operational screens used by internal teams. Worked on improving validation logic, usability, and the handling of request-driven workflows so that the application could better support day-to-day internal processes with fewer interruptions and more predictable behavior.
- Participated in debugging, testing, and issue resolution during development and review cycles. Investigated application issues, supported fixes, verified workflow behavior, and contributed to improving functional stability across internal modules. This experience helped me build stronger fundamentals in troubleshooting, validating software behavior, and working carefully within process-oriented systems.
- Collaborated with team members to understand requirements, implement updates, and support internal reviews in a disciplined technical setting. The internship strengthened my foundation in software engineering, exposed me to enterprise-style workflow systems, and helped me develop a more detail-oriented approach to implementation, testing, and support.

PROJECTS

AI Resume Matching and Retrieval Platform

2025

Python, FastAPI, PostgreSQL, Azure OpenAI, Azure AI Search, RAG

- Built an end-to-end retrieval and recommendation platform designed to process resumes and job descriptions, generate embeddings, index content for semantic retrieval, and return ranked matches between candidates and roles. The project was centered on solving a practical hiring workflow problem by moving beyond simple keyword matching and toward retrieval-driven relevance based on context, skills, and role alignment.
- Designed the pipeline to handle document ingestion, parsing, chunking, embedding generation, retrieval, and LLM-assisted ranking. Focused on making the system modular so that each stage of the workflow could be improved independently, whether at the level of document processing quality, retrieval relevance, ranking logic, or response generation.
- Implemented semantic search and prompt orchestration patterns that improved the quality of candidate-job recommendations and made the system more useful for screening-oriented workflows. The project strengthened my experience in combining backend engineering, structured data handling, and AI retrieval workflows into a single application that solved a real business use case.

ML Video Highlight Extraction and Feedback Loop

2025

Python, OpenCV, Transformers, Whisper, FFmpeg, Gradio

- Developed a machine learning pipeline for long-form video analysis that identified candidate highlight moments by combining transcript signals, timing logic, and content-scoring heuristics. The goal of the project was to reduce the manual effort required to review full-length videos and make it easier to generate shorter, more engaging clips from larger content sources.
- Built workflow components for transcription, highlight candidate selection, clip generation, and reviewer feedback collection. Instead of treating the system as a one-time pipeline, I designed it with iteration in mind so that reviewer input could be incorporated back into the workflow and used to refine future highlight selection behavior.
- This project gave me hands-on experience with applied machine learning, media processing, and feedback-driven system improvement. It also strengthened my ability to think about model usefulness from a product perspective, where the quality of the output depended not just on the model itself but on how well the surrounding pipeline supported evaluation and continuous refinement.

Traktive AI

2025

React, TypeScript, Vite, Gemini, Recharts

- Built an AI-powered productivity application that processed calendar exports and task inputs to generate structured daily plans, focused work blocks, and personalized scheduling recommendations. The project was designed around the idea that AI should not just generate text, but help turn scattered inputs into more practical, organized decision support for daily execution.
- Integrated Gemini using structured outputs so that the generated plans were more consistent and easier to render within the application. Also developed analytics views that highlighted task completion patterns, time usage trends, and productivity-related summaries, making the product more actionable for users who wanted both recommendations and visibility into their behavior over time.
- The project strengthened my frontend and AI integration skills by combining interface design, structured data handling, visualization, and intelligent recommendation logic into a cohesive user-facing product.

anvikshiki.ai

Nov 2025 – Present

Next.js, Python, FastAPI, PostgreSQL, LLMs, RAG

- Designing an AI-driven personal intelligence platform that analyzes daily phone and wearable activity to understand user behavior patterns and generate personalized next-day recommendations. The broader goal of the platform is to convert passive personal data into useful, privacy-aware insights that can help improve routine quality, focus, and energy management.

- Defined the MVP architecture for ingestion, storage, pattern analysis, summarization, embeddings, retrieval, and recommendation generation. Focused on how different layers of the system should work together so that raw user signals can be transformed into structured memory, usable context, and meaningful recommendation outputs.
- This project reflects my long-term interest in building intelligent systems that are not only technically strong but also deeply user-centric. It has helped me think more seriously about product architecture, privacy-aware design, long-horizon AI workflows, and the practical challenges of building systems that continuously learn from real-world behavior.

EDUCATION

University of Massachusetts Lowell

M.S. in Computer Science

May 2025

Lowell, MA

CVR College of Engineering

B.Tech in Computer Science

May 2023

Hyderabad, India

CERTIFICATIONS

- AWS Certified Developer – Associate
- Full Stack Development with React Js & Node Js
- Broadridge India Innovation Hackathon Winner
